Bioactive substrates are capable of enhancing proliferation of osteoblast cells, since these cells transduce changes in the mechanical environment. This study investigates the effect of mechano-transduction through substrate characterization on proliferation of osteoblast-like (MC3T3-E1) cells. It is a fundamental study on the effect of mechanotransduction in bone cells through functionalised silastic bioactive nano-substrates. Strains occur in bone cells as a result of mechano-stimulus under physiological conditions [1] and the strain rate correlate with bone formation [2], since the mechanical forces are transmitted to cells through the ECM [3, 4] which results in immediate early gene expression and proliferation of MC3T3-E1 osteoblasts cells. Osteoblast cells were anchored to a chemically functionalized substrate to ascertain whether application of equibiaxial mechano-stimulus could change the cytoskeletal architecture of the cells. The membrane was functionalized, characterized using CA goniometry, RBS (fig. a) and AFM (fig. b). MC3T3-E1 cells were seeded onto the nano-scale biomimetic surface and subjected to mechanical deformation, after which cellular functions were evaluated, by CM, to determine changes in the cytoskeletal organization of the adherent cells. Application of biophysical forces to biological systems, according to Frost mechanostatic theory, translates into cellular responses, under physiological conditions; since cellular organisms tend to adapt to their mechanical environment. There were noticeable changes in the cytoskeletal architecture of MC3T3-E1 cells (fig. c) after subjecting them to the dynamic equibiaxial strains, with minimum cell damage, indicating that functionalised nano-surfaces transduced mechanical stimuli onto osteoblast-like cells. We engineered a system which mechanically transduces strains in nano-structured surfaces to enhance cytoskeletal architecture of osteoblast-like bone cells.
